

AN INTRODUCTION TO PAIR-COPULA CONSTRUCTIONS

Ramiro Ruiz Cárdenas

**1º Workshop do projeto PROCAD:
Seguro Agrícola: Modelagem Estatística e Precificação**

UFMG - Belo Horizonte, Novembro 25-27 de 2009

Multivariate Distributions

Consider n random variables $X = (X_1, \dots, X_n)$ with

- joint density $f(x_1, \dots, x_n)$ and marginal densities $f_i(x_i)$, $i = 1, \dots, n$
- joint cdf $F(x_1, \dots, x_n)$ and marginal cdf's $F_i(x_i)$, $i = 1, \dots, n$
- $f(. | .)$ denote corresponding conditional densities

and consider the factorization

$$\begin{aligned} f(x_1, \dots, x_n) &= f(x_n | x_1, \dots, x_{n-1}) \cdot f(x_1, \dots, x_{n-1}) \\ &= \left[\prod_{t=2}^n f(x_t | x_1, \dots, x_{t-1}) \right] \cdot f_1(x_1) \end{aligned}$$

Copula

A copula is a multivariate distribution on $[0, 1]^n$ with uniformly distributed marginals.

- copula cdf $C(u_1, \dots, u_n)$
- copula density $c(u_1, \dots, u_n)$

Using Sklar's Theorem (1959) we have for absolutely continuous **bivariate** distributions with continuous marginal cdf's

$$f(x_1, x_2) = c_{12}(F_1(x_1), F_2(x_2)) \cdot f_1(x_1) \cdot f_2(x_2)$$
$$f(x_1 | x_2) = c_{12}(F_1(x_1), F_2(x_2)) \cdot f_1(x_1)$$

for some bivariate copula density $c_{12}(\cdot)$.

Pair-copula constructions (PCC)

- Multivariate data can be modelled using a cascade of pair-copulae, acting on two variables at a time.
- The basic idea is to decompose an arbitrary distribution function into simple bivariate building blocks and stitch them together appropriately.
- These bivariate blocks are two-dimensional copulas and we have a large selection to choose from.

The two dimensional case

For the base case in two dimensions we can easily see that

$$f(x_1, x_2) = c_{12}(F_1(x_1), F_2(x_2)) \cdot f_1(x_1) \cdot f_2(x_2)$$

$$F(x_1, x_2) = C(F_1(x_1), F_2(x_2))$$

$$f_{2|1}(x_2|x_1) = \frac{f(x_1, x_2)}{f_1(x_1)} = c_{12}(F_1(x_1), F_2(x_2)) \cdot f_2(x_2)$$

The three dimensional case

- Any three-dimensional density function can be written in the form

$$f(x_1, x_2, x_3) = f_1(x_1) \cdot f_{2|1}(x_2|x_1) \cdot f_{3|1,2}(x_3|x_1, x_2)$$

- we can write $f_{2|1}(x_2|x_1) = c_{12}(F_1(x_1), F_2(x_2)) \cdot f_2(x_2)$

- conditioning in X_2 , we have that

$$f_{3|1,2}(x_3|x_1, x_2) = c_{13|2}(F_{1|2}(x_1|x_2), F_{3|2}(x_3|x_2)) \cdot f_{3|2}(x_3|x_2)$$

- This yields the full decomposition

$$\begin{aligned} f(x_1, x_2, x_3) &= f_1(x_1) \cdot \\ &\quad c_{12}(F_1(x_1), F_2(x_2)) f_2(x_2) \cdot \\ &\quad c_{13|2}(F_{1|2}(x_1|x_2), F_{3|2}(x_3|x_2)) \cdot c_{23}(F_2(x_2), F_3(x_3)) \cdot f_3(x_3) \end{aligned}$$

The four dimensional case

- For a four-dimensional density we start with

$$f(x_1, x_2, x_3, x_4) = f_1(x_1) \cdot f_{2|1}(x_2|x_1) \cdot f_{3|1,2}(x_3|x_1, x_2) \cdot f_{4|1,2,3}(x_4|x_1, x_2, x_3)$$

- and rewrite it in terms of six pair-copulas and the four marginal densities $f_i(x_i)$ for $i = 1, 2, 3, 4$:

$$\begin{aligned} f(x_1, x_2, x_3, x_4) = & f_1(x_1) \cdot \\ & c_{12}(F_1(x_1), F_2(x_2)) \cdot f_2(x_2) \cdot \\ & c_{23|1}(F_{2|1}(x_2|x_1), F_{3|1}(x_3|x_1)) \cdot c_{13}(F_1(x_1), F_3(x_3)) \cdot f_3(x_3) \cdot \\ & c_{34|12}(F_{3|12}(x_3|x_1, x_2), F_{4|12}(x_4|x_1, x_2)) \cdot \\ & c_{24|1}(F_{2|1}(x_2|x_1), F_{4|1}(x_4|x_1)) \cdot \\ & c_{14}(F_1(x_1), F_4(x_4)) \cdot f_4(x_4) \end{aligned}$$

Pair-copula constructions (PCC)

- For distinct i, j, i_1, \dots, i_k with $i < j$ and $i_1 < \dots < i_k$ let

$$C_{i,j|i_1, \dots, i_k} := C_{i,j|i_1, \dots, i_k}(F(x_i | x_{i_1}, \dots, x_{i_k}), (F(x_j | x_{i_1}, \dots, x_{i_k})))$$

- Reexpress $f(x_t | x_1, \dots, x_{t-1})$ as

$$\begin{aligned} f(x_t | x_1, \dots, x_{t-1}) &= C_{1,t|2, \dots, t-1} \cdot f(x_t | x_1, \dots, x_{t-2}) \\ &= \left[\prod_{s=1}^{t-2} C_{s,t|s+1, \dots, t-1} \right] \cdot C_{(t-1),t} \times f_t(x_t) \end{aligned}$$

- Using (1) and $s = i, t = i + j$ it follows that

$$\begin{aligned} f(x_1, \dots, x_n) &= \left[\prod_{t=2}^n \prod_{s=1}^{t-2} C_{s,t|s+1, \dots, t-1} \right] \cdot \left[\prod_{t=2}^n C_{(t-1),t} \right] \left[\prod_{k=1}^n f_k(x_k) \right] \\ &= \left[\prod_{j=1}^{n-1} \prod_{i=1}^{n-j} C_{i,(i+j)|(i+1), \dots, (i+j-1)} \right] \cdot \left[\prod_{k=1}^n f_k(x_k) \right] \end{aligned}$$

Marginal conditional distributions

- many of the pair-copulas need to be evaluated at a conditional distribution of the form $F(x|\mathbf{v})$, where \mathbf{v} denotes a vector of variables.
- The calculation of these conditional distributions is also recursive.
- Let \mathbf{v}_{-j} denote the vector \mathbf{v} but excluding the j th component v_j . For every j ,

$$F(x|\mathbf{v}) = \frac{\partial C_{x,v_j|\mathbf{v}_{-j}}(F(x|\mathbf{v}_{-j}), F(v_j|\mathbf{v}_{-j}))}{\partial F(v_j|\mathbf{v}_{-j})}$$

where $C_{x,v_j|\mathbf{v}_{-j}}$ is a bivariate copula function.

- For the special case where \mathbf{v} has only one component we have

$$F(x|\mathbf{v}) = \frac{\partial C_{x,v}(F_x(X), F_v(V))}{\partial F_v(V)}$$

Pair-Copula Constructions and Vines

- The above decomposition is called a pair-copula construction (PCC).
- The decomposition is not unique. That is, for high-dimensional distributions there are many possible pair-copula constructions.
- Bedford and Cooke (2002) introduced a **graphical model** called **regular vine** that help us organize a subset of all possible decompositions.
- The class of regular vines is large and embraces a large number of possible PCC's. Two special cases are:
 - **D-Vine**
 - **Canonical Vine**

Both consists of sequences of trees that show us how to write a joint density function into pair-copulas and marginal densities

Canonical Vine Representation

$$\begin{aligned}
 f(x_1, x_2, x_3, x_4) &= f_1(x_1)f_2(x_2)f_3(x_3)f_4(x_4) \\
 &\quad c_{31}(F_3(x_3), F_1(x_1))c_{32}(F_3(x_3), F_2(x_2))c_{34}(F_3(x_3), F_4(x_4)) \\
 &\quad c_{21|3}(F_{2|3}(x_2|x_3), F_{1|3}(x_1|x_3))c_{24|3}(F_{2|3}(x_2|x_3), F_{4|3}(x_4|x_3)) \\
 &\quad c_{14|23}(F_{1|23}(x_1|x_2, x_3), F_{4|23}(x_4|x_2, x_3))
 \end{aligned}$$

The intuition behind canonical vines is that one variable plays a key role in the dependency structure and so everyone is linked to it.

D-Vine Representation

$$\begin{aligned} f(x_1, x_2, x_3, x_4) &= f_1(x_1)f_2(x_2)f_3(x_3)f_4(x_4) \\ & c_{12}(F_1(x_1), F_2(x_2))c_{23}(F_2(x_2), F_3(x_3))c_{34}(F_3(x_3), F_4(x_4)) \\ & c_{13|2}(F_{1|2}(x_1|x_2), F_{3|2}(x_3|x_2))c_{24|3}(F_{2|3}(x_2|x_3), F_{4|3}(x_4|x_3)) \\ & c_{14|23}(F_{1|23}(x_1|x_2, x_3), F_{4|23}(x_4|x_2, x_3)) \end{aligned}$$

Estimating the Pair-Copula Decomposition

The canonical or D-vine constructions decompose an n -dimensional multivariate density function into two main components.

- the product of each of the marginal density functions.
- the product of the density functions of $n(n-1)/2$ bivariate copulas.

To estimate the parameters of either construction we need to

- 1 decide which family to use for each pair-copula and
- 2 estimate all necessary parameters simultaneously

chi-plots (Fischer and Switzer, 1985)

- A chi-plot is a graphical method to help us extract information about the dependence between two random variables.
- The essence of the chi-plot is to compare the empirical bivariate distribution against the null hypothesis of independence at each point in the scatterplot.
- To construct this plot from a set of points $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$ we calculate three empirical distribution functions: the bivariate distribution H and the two marginal distributions F and G .
- For each point (x_i, y_i) let H_i be the proportion of points below and to the left of (x_i, y_i) . Also let F_i and G_i be the proportion of points to the left and below of the point (x_i, y_i) , respectively.

chi-plots (Fischer and Switzer (1985))

Each point (χ_i, λ_i) of the χ -plot is then defined by

$$\chi_i = \frac{H_i - F_i G_i}{\sqrt{F_i(1-F_i)G_i(1-G_i)}} \quad (24)$$

and

$$\lambda_i = 4S_i \max \left\{ \left(F_i - \frac{1}{2} \right)^2, \left(G_i - \frac{1}{2} \right)^2 \right\}, \quad (25)$$

where

$$S_i = \text{sign} \left\{ \left(F_i - \frac{1}{2} \right) \left(G_i - \frac{1}{2} \right) \right\}. \quad (26)$$

The formal definitions for H , F and G are

$$H_i = \frac{1}{n-1} \sum_{j \neq i} I(x_j \leq x_i, y_j \leq y_i), \quad (27)$$

$$F_i = \frac{1}{n-1} \sum_{j \neq i} I(x_j \leq x_i), \quad (28)$$

$$G_i = \frac{1}{n-1} \sum_{j \neq i} I(y_j \leq y_i), \quad (29)$$

chi-plots (Fischer and Switzer (1985))
